## Applications in Genetics and Epigenetics

Nuno Sepúlveda, 01.12.2025

# Syllabus

## 1. General review

- a. Population/Sample/Sample size
- b. Type of Data – quantitative and qualitative variables
- c. Common probability distributions/popular tests

## 2. Applications in Medicine

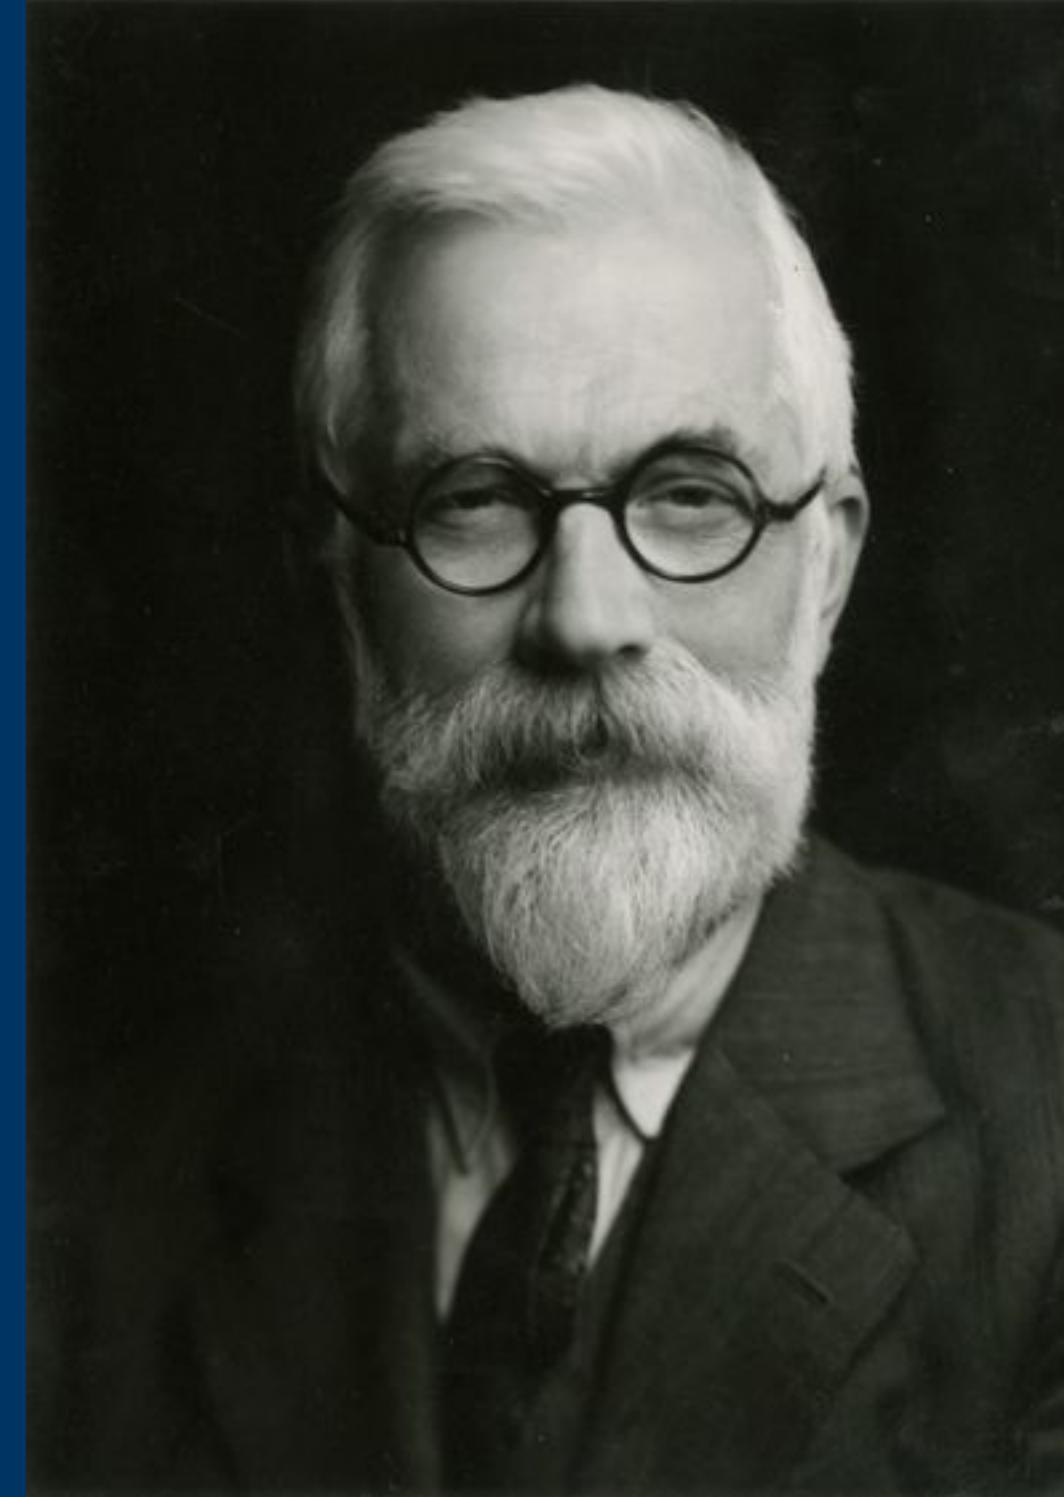

- a. Construction and analysis of diagnostic tools – Binomial distribution, ROC curve, sensitivity, specificity, Rogal-Gladen estimator
- b. Estimation of treatment effects - generalized linear models
- c. Survival analysis - Kaplan-Meier curve, log-rank test, Cox's proportional hazards model

## 3. Applications in Genetic and Epigenetic Data

- a. Genetic association studies – Hardy-Weinberg test, homozygosity, minor allele frequencies, additive model, multiple testing correction
- b. Methylation association studies – M versus beta values, estimation of biological age

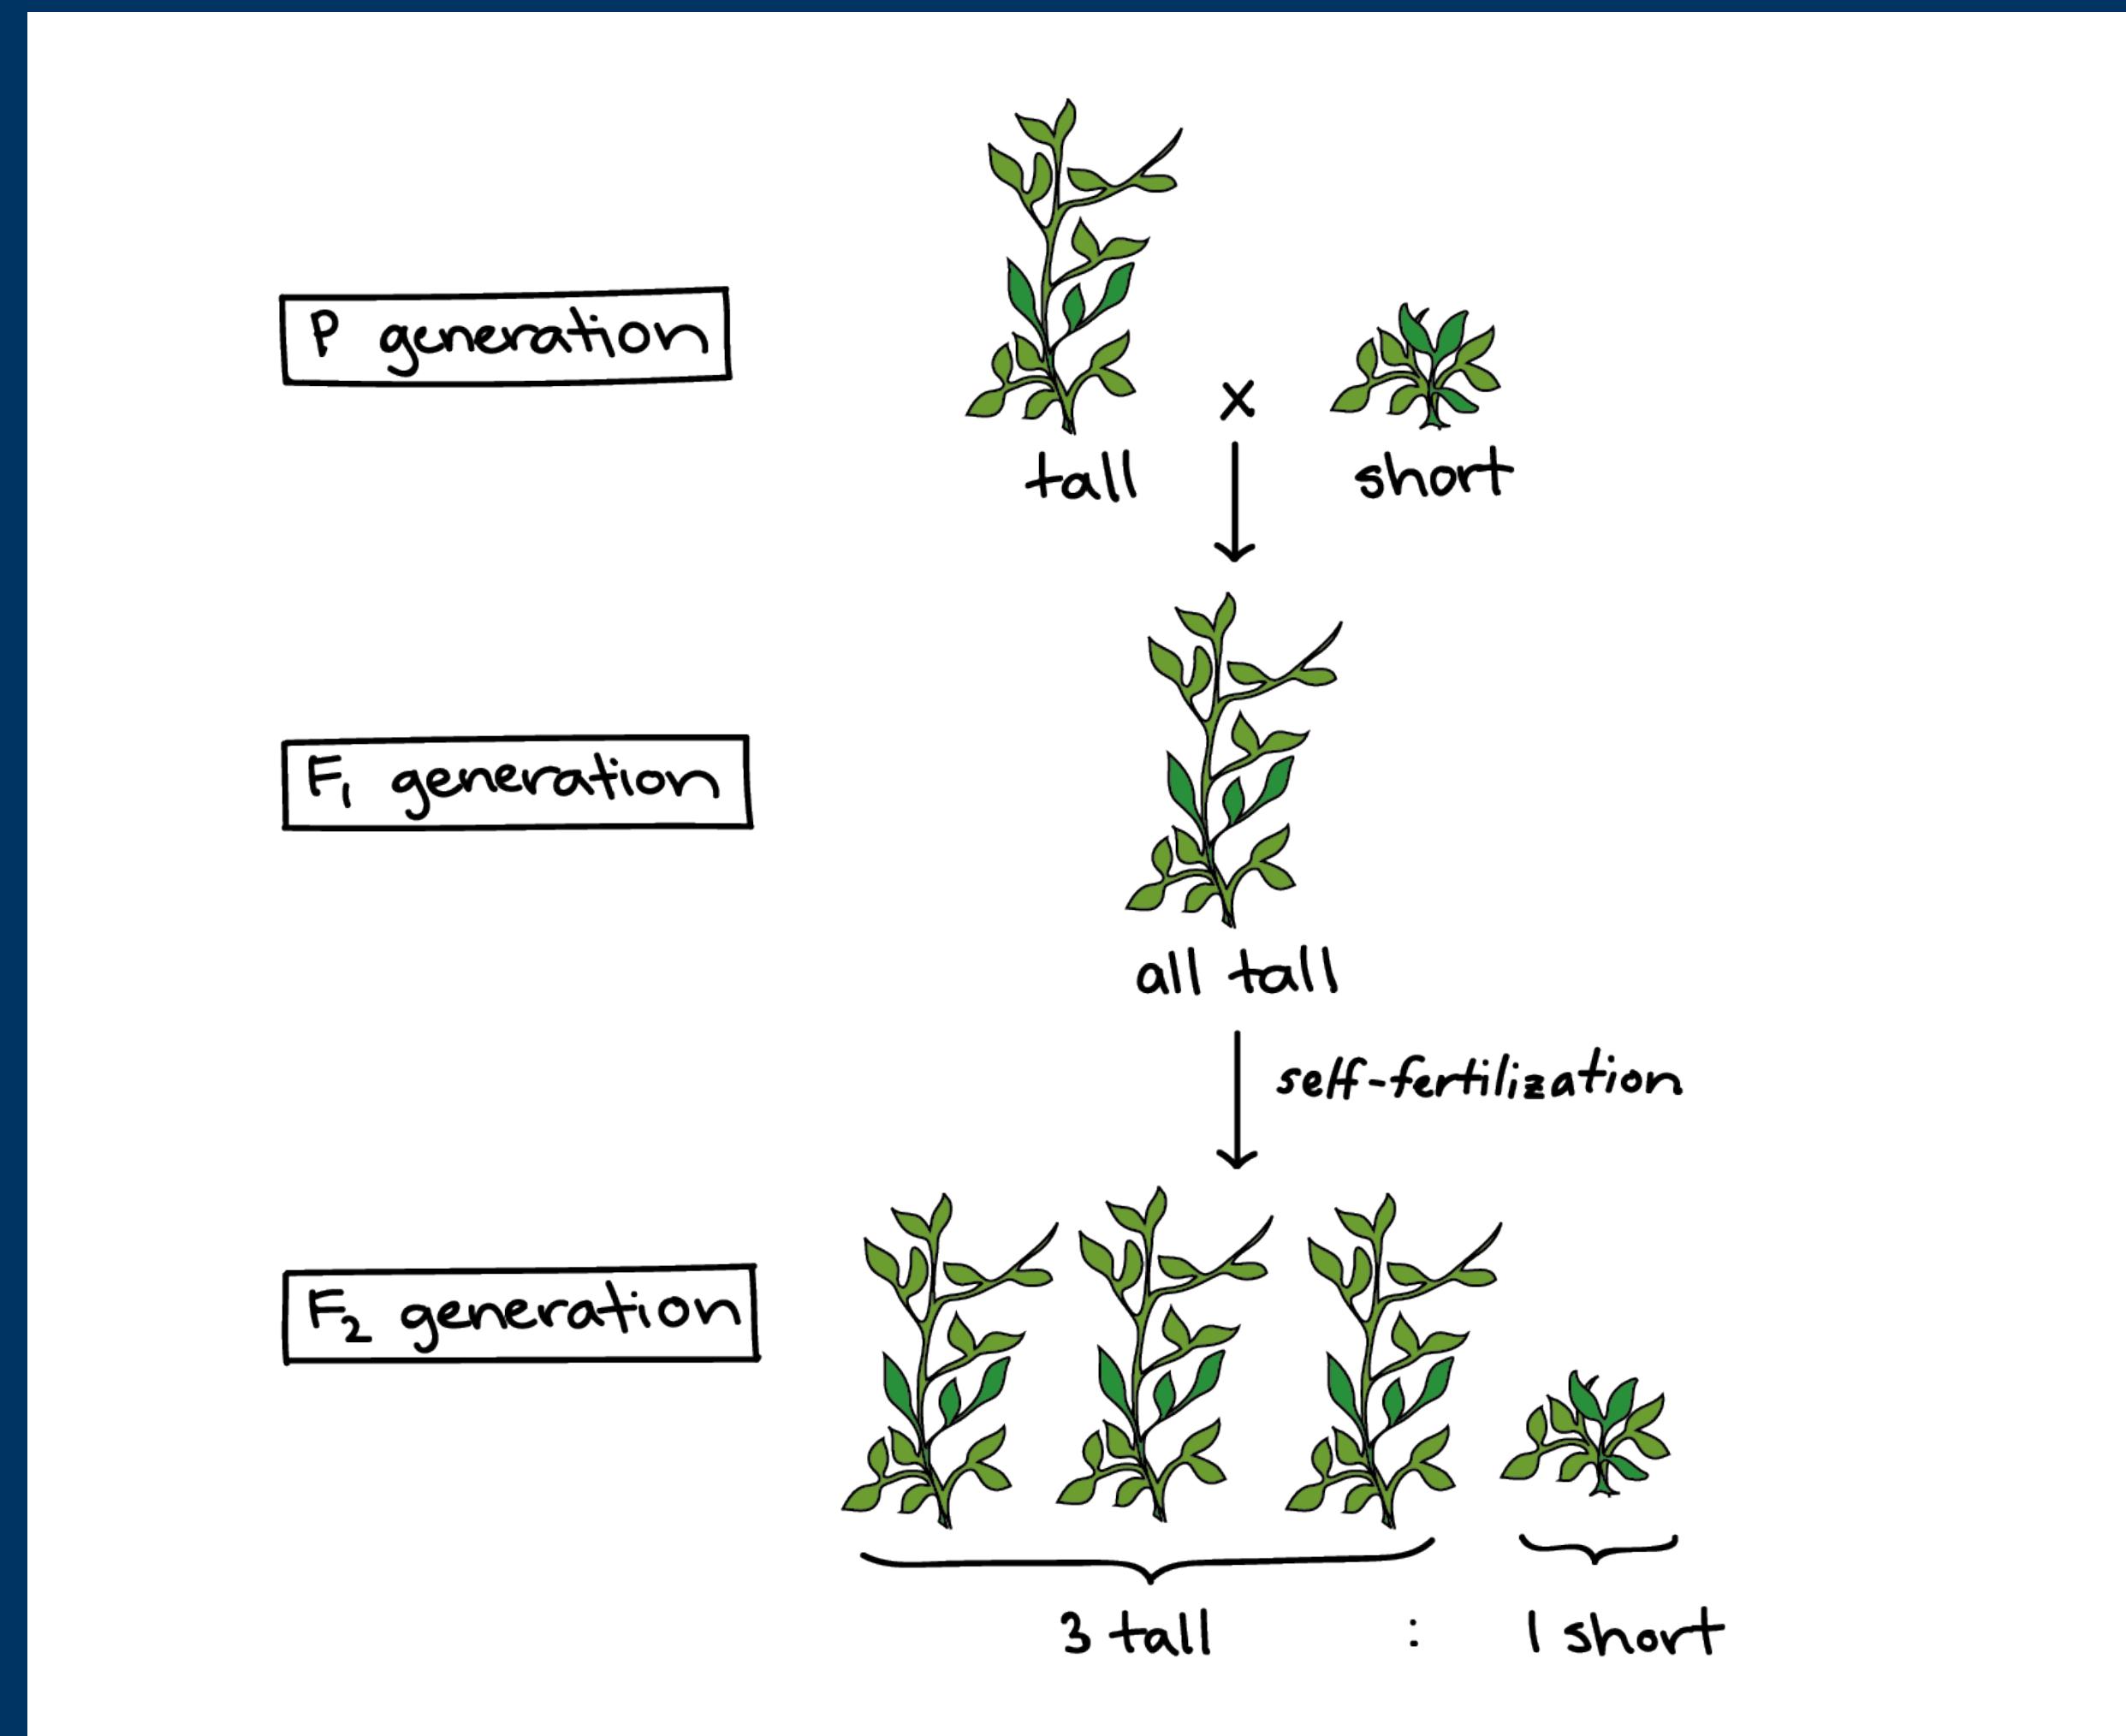

## 4. Applications in Serological Data Analysis

- a. Determination of seropositivity using Gaussian mixture models
- b. Reversible catalytic models for estimating seroconversion rate
- c. Sample size calculation for estimating seroconversion rate

# First two Mendel's laws

## The law of Dominance and Uniformity

Some alleles are dominant over the other alleles for a given gene

## The law of Segregation

Two alleles for each gene separate from each other during gametogenesis so that the parent may only pass off one allele; thus, the offspring can only inherit one allele from each parent

# Exercise 1: data\_mendel\_single\_trait.csv

TABLE 1

*Data given in Mendel (1866) for the single trait experiments. “A” (“a”) denotes the dominant (recessive) phenotype; A (a) denotes the dominant (recessive) allele; n is the total number of observations per experiment (that is, seeds for the seed trait experiments and plants otherwise); n“A”, n“a”, n<sub>Aa</sub> and n<sub>AA</sub> denote observed frequencies*

|                       | Trait           | “A”      | “a”         | n    | Obs. freq. |      | Theor. ratio |
|-----------------------|-----------------|----------|-------------|------|------------|------|--------------|
|                       |                 |          |             |      | n“A”       | n“a” | “A” : “a”    |
| <i>F</i> <sub>2</sub> | Seed shape      | round    | wrinkled    | 7324 | 5474       | 1850 | 3 : 1        |

| <b>Total</b> | 138       | 265       | 126       | 529          |

Test the third Mendel's law predictions for each trait using an appropriate statistical test.

Draw your conclusions.

# Mendel-Fisher Controversy

144

## HAS MENDEL'S WORK BEEN REDISCOVERED ? \*

By R. A. FISHER, M.A., Sc.D., F.R.S.,

*Galton Professor of Eugenics, University College, London.*

### 1. THE POLEMIC USE OF THE REDISCOVERY.

THE tale of Mendel's discovery of the laws of inheritance, and of the sensational rediscovery of his work thirty-four years after its publication and sixteen after Mendel's death, has become traditional in the teaching of biology. A careful scrutiny can but strengthen the truth in such a tradition, and may serve to free it from such accretions as prejudice or hasty judgment may have woven into the story. Few statements are so free from these errors as that which I quote from H. F. Roberts' valuable book *Plant Hybridisation before Mendel* (p. 286) :

"The year 1900 marks the beginning of the modern period in the study of heredity. Despite the fact that there had been some development of the idea that a living organism is an aggregation of characters in the form of units of some description, there had been no attempts to ascertain by experiment, how such supposed units might behave in the offspring of a cross. In the year above mentioned the papers of Gregor Mendel came to light, being quoted almost simultaneously in the scientific contributions of three European botanists, De Vries in Holland, Correns in Germany, and Von Tschermak in Austria. Of Mendel's two papers, the important one in this connection, entitled ' Experiments in Plant Hybridization ', was read at the meetings of the Natural History Society of Brünn in Bohemia (Czecho-Slovakia) at the sessions of February 8 and March 8, 1865. This paper had passed entirely unnoticed by the scientific circles of Europe, although it appeared in 1866 in the Transactions of the Society. From its publication until 1900, Mendel's paper appears to have been completely overlooked, except for the citations in Focke's ' Pflanzenmischlinge ', and the single citation of Hoffmann, elsewhere referred to."

\* For further commentary on Mendel's work written by Fisher in 1955, see *Experiments in Plant Hybridisation: Gregor Mendel*. (Ed. J.H. Bennett) Edinburgh: Oliver & Boyd, 1965. As indicated there, all of the years given in Fisher's (1936) reconstruction of the timing of Mendel's experimental programme must be reduced by one.

detail by his paper as a whole. Although no explanation can be expected to be satisfactory, it remains a possibility among others that Mendel was deceived by some assistant who knew too well what was expected. This possibility is supported by independent evidence that the data of most, if not all, of the experiments have been falsified so as to agree closely with Mendel's expectations.

## A Statistical Model to Explain the Mendel–Fisher Controversy

Ana M. Pires and João A. Branco

**Abstract.** In 1866 Gregor Mendel published a seminal paper containing the foundations of modern genetics. In 1936 Ronald Fisher published a statistical analysis of Mendel's data concluding that “*the data of most, if not all, of the experiments have been falsified so as to agree closely with Mendel's expectations.*” The accusation gave rise to a controversy which has reached the present time. There are reasonable grounds to assume that a certain unconscious bias was systematically introduced in Mendel's experimentation. Based on this assumption, a probability model that fits Mendel's data and does not offend Fisher's analysis is given. This reconciliation model may well be the end of the Mendel–Fisher controversy.

**Key words and phrases:** Genetics, ethics, chi-square tests, distribution of *p*-values, minimum distance estimates.

### Exercise 3:

$$X \rightsquigarrow F \Rightarrow \begin{cases} Y = F(X) \rightsquigarrow \text{Uniform}(0,1) \\ Y = 1 - F(X) \rightsquigarrow \text{Uniform}(0,1) \end{cases}$$

Create a pooled sample of the p-values from exercises 1 and 2 and test whether the p-values are coming from an Uniform distribution.

Draw your conclusions.

# First creation of Genotype-Mapping

If you know the genotype, then you know the phenotype

One gene that controls a single binary trait

# Mendel triggered the scientific curiosity

What is actually a gene and an allele?

What is the gene involved?

Is it possible to derive genotype-phenotype rules for other type of traits such as the occurrence of a given disease or height?

## Some useful concepts

Gene = a stretch of DNA located in a chromosome. The stretches encodes a protein

Allele = variant in the DNA sequence of a gene

Chromosome = a long DNA molecule that contains genetic information of an organism

Genome = the set of all the chromosomes that enables the creation of life

Human Genome = 1-23 autosomal chromosomes, X and Y sexual chromosomes

# Beyond Mendelian

Genotype  $\longrightarrow$  Phenotype Probabilities

$\pi_{aa}$

Complete penetrance versus incomplete penetrance

What is the gene responsible for this trait?

# Genetic mapping: general principle

What is the gene responsible for this trait?

Use experimental cross a la Mendel.

Use genetic markers (with alleles a and b) at known location in the genome.

Test for association between the genotypes and the trait.

# Example: Genetic mapping of Type 1 diabetes in mice

## Discussion:

What is the statistical challenge of genetic mapping?

# Multiple testing problem

In absence of association

$\alpha = 0.05$        $m =$  number of genetic markers (statistical tests)

$Y =$  Number of significant tests  $| H_0, \alpha = 0.05 \rightsquigarrow \text{Binomial}(m, p = \alpha)$

Expected number of false positive associations

$$E[Y | H_0, \alpha] = m \times \alpha$$

$$E[Y | H_0, \alpha] = 53 \times 0.05 = 2.65$$

# Dealing with multiple testing (classical methods)

Redefine the type I error for the overall analysis

$$P[Y \geq 1 | H_0, \alpha^*] = \alpha$$

$$E[Y | H_0, \alpha^*] = \alpha$$

$$1 - (\alpha^*)^m = \alpha \Leftrightarrow \alpha^* = 1 - (1 - \alpha)^{1/m}$$

$$m \times \alpha^* = \alpha \Leftrightarrow \alpha^* = \frac{\alpha}{p}$$

Sidak-Dunn correction

$$\alpha^* = 1 - (1 - \alpha)^{1/53} \approx 0.00084$$

Bonferroni correction

$$\alpha^* = \frac{0.05}{53} = 0.00082$$

In the previous exercise, was the strongest association statistically significant controlling for multiple testing?

# Mendelian Genetics

Single gene, single binary trait

Complete penetrance

Rules of dominance/recessiveness

# Non-Mendelian Genetics

Complex binary traits

Presence of common diseases (diabetes, multiple sclerosis, COVID-19 lethality)

Categorical traits

Eye color

Multiple interacting gene involved

Quantitative traits

Height, Haemoglobin levels, blood pressure

## Basic question

What are the genes involved and what is their action on the phenotype?

The identification of the genes involved is expected to improve human health by targeting the causative genes

# Recombination

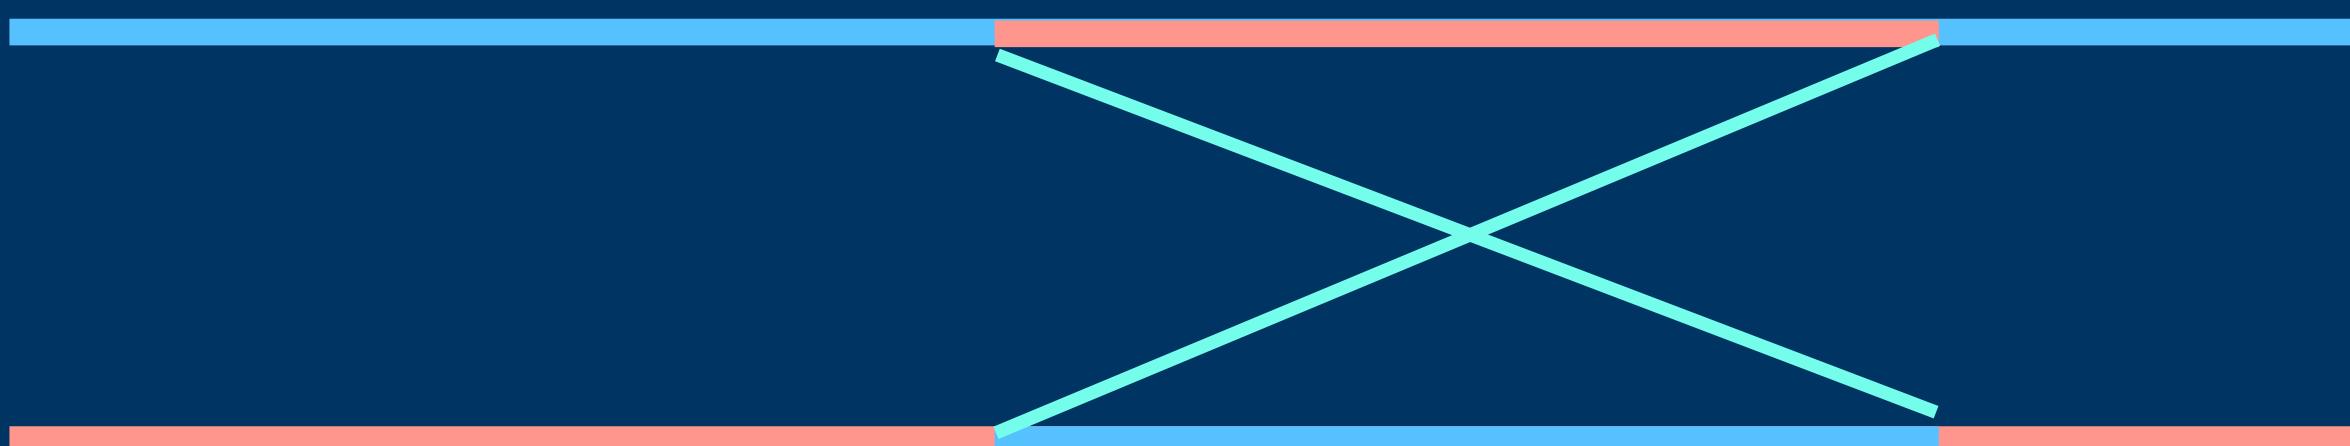

Paternal  
Chromosome a

Maternal  
Chromosome a

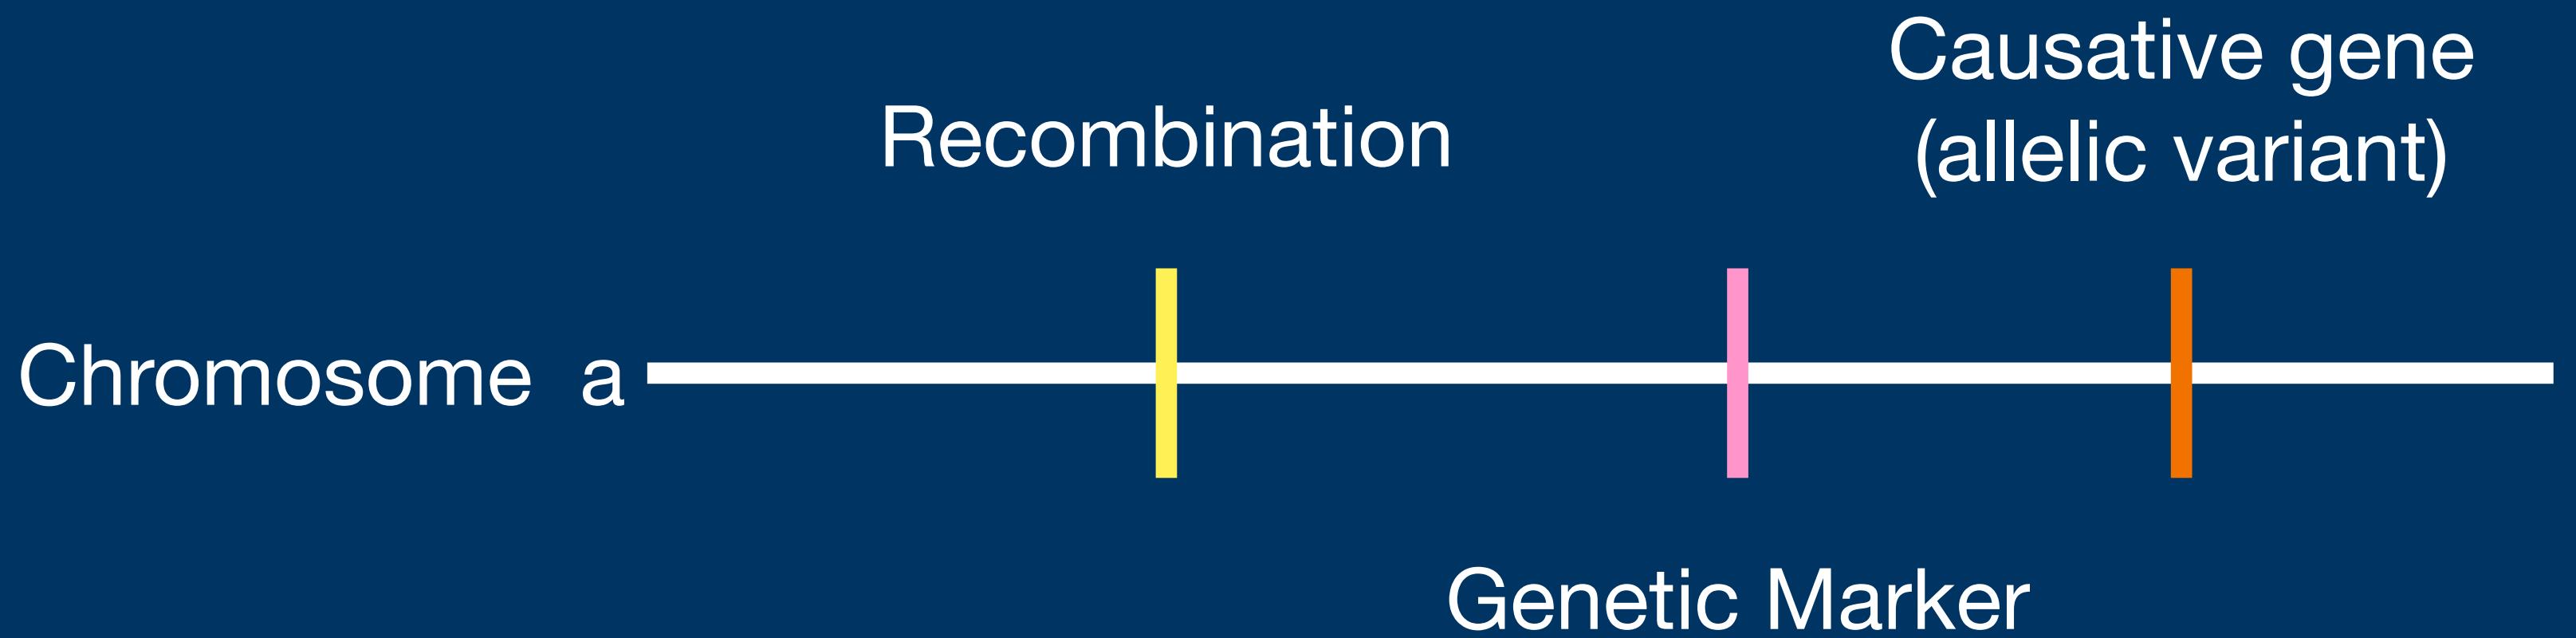

During formation of  
gametes (sperm/egg  
cells)

# Linkage and recombination

## Complete linkage

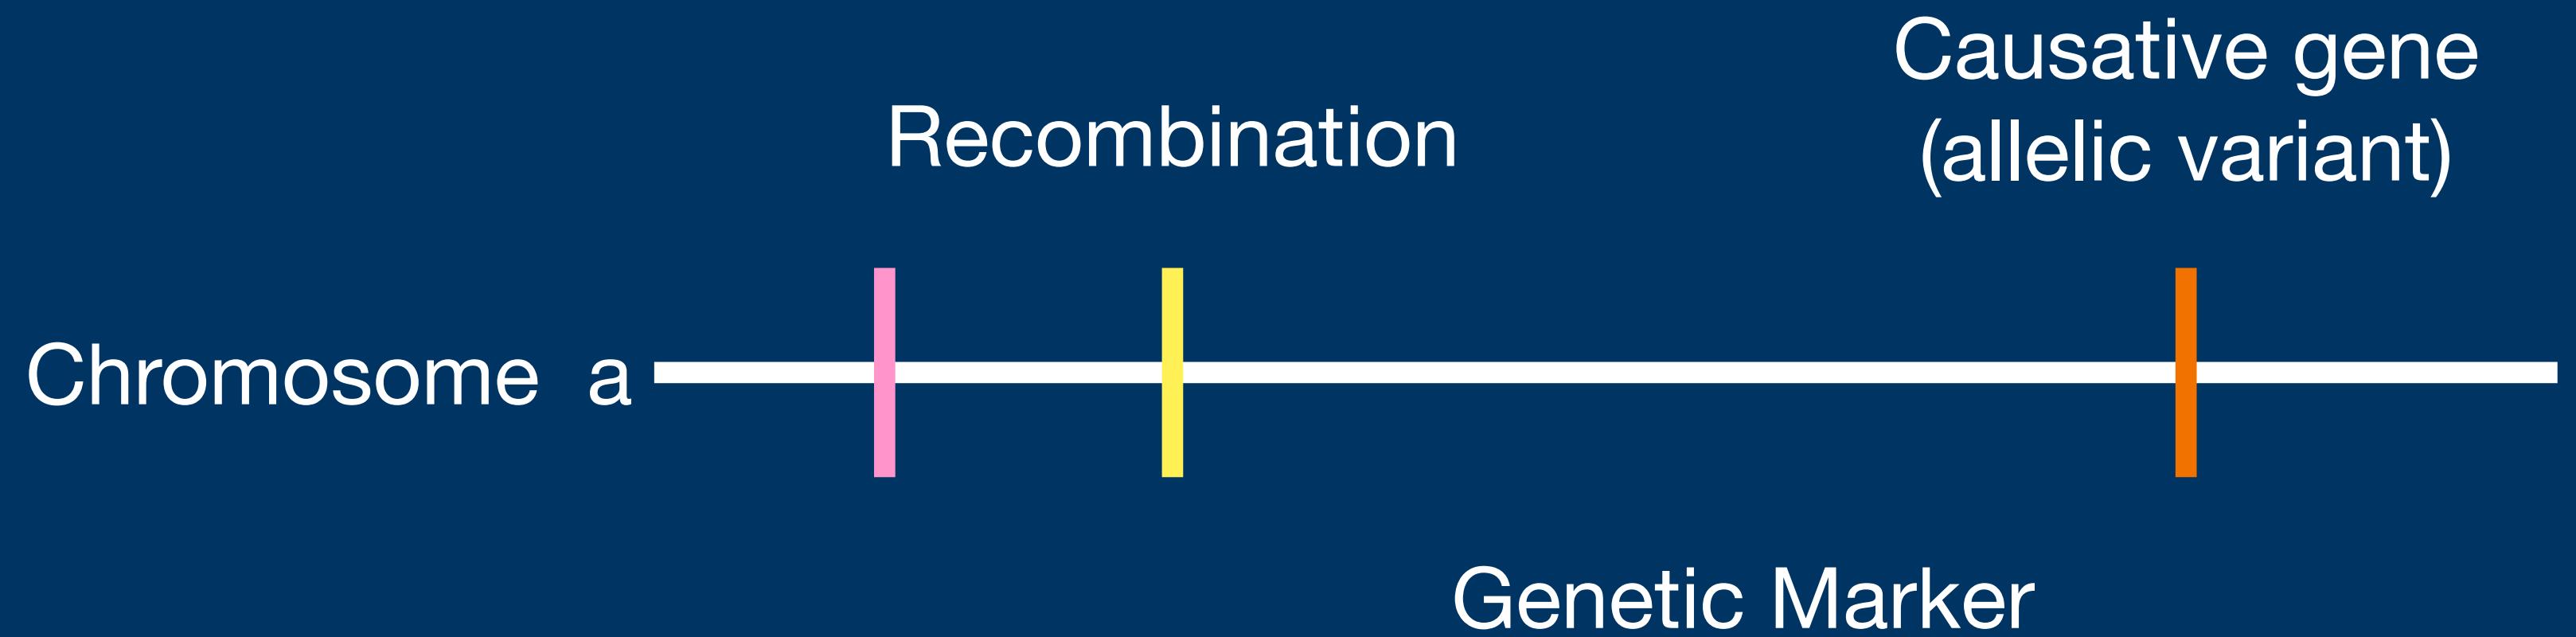

If a genetic marker and the causative gene are physically close to each other, then the genetic marker and the gene are inherited together.

The genetic marker fully represents the true statistical association between the causative gene and the phenotype.

# Linkage and recombination

## Incomplete linkage

If a genetic marker and the causative gene are not physically close to each other, then a recombination might occur during gametogenesis. This recombination is passed onto the offsprings

The genetic marker partially represents the true statistical association between the causative gene and the phenotype.

# Linkage and recombination

No linkage

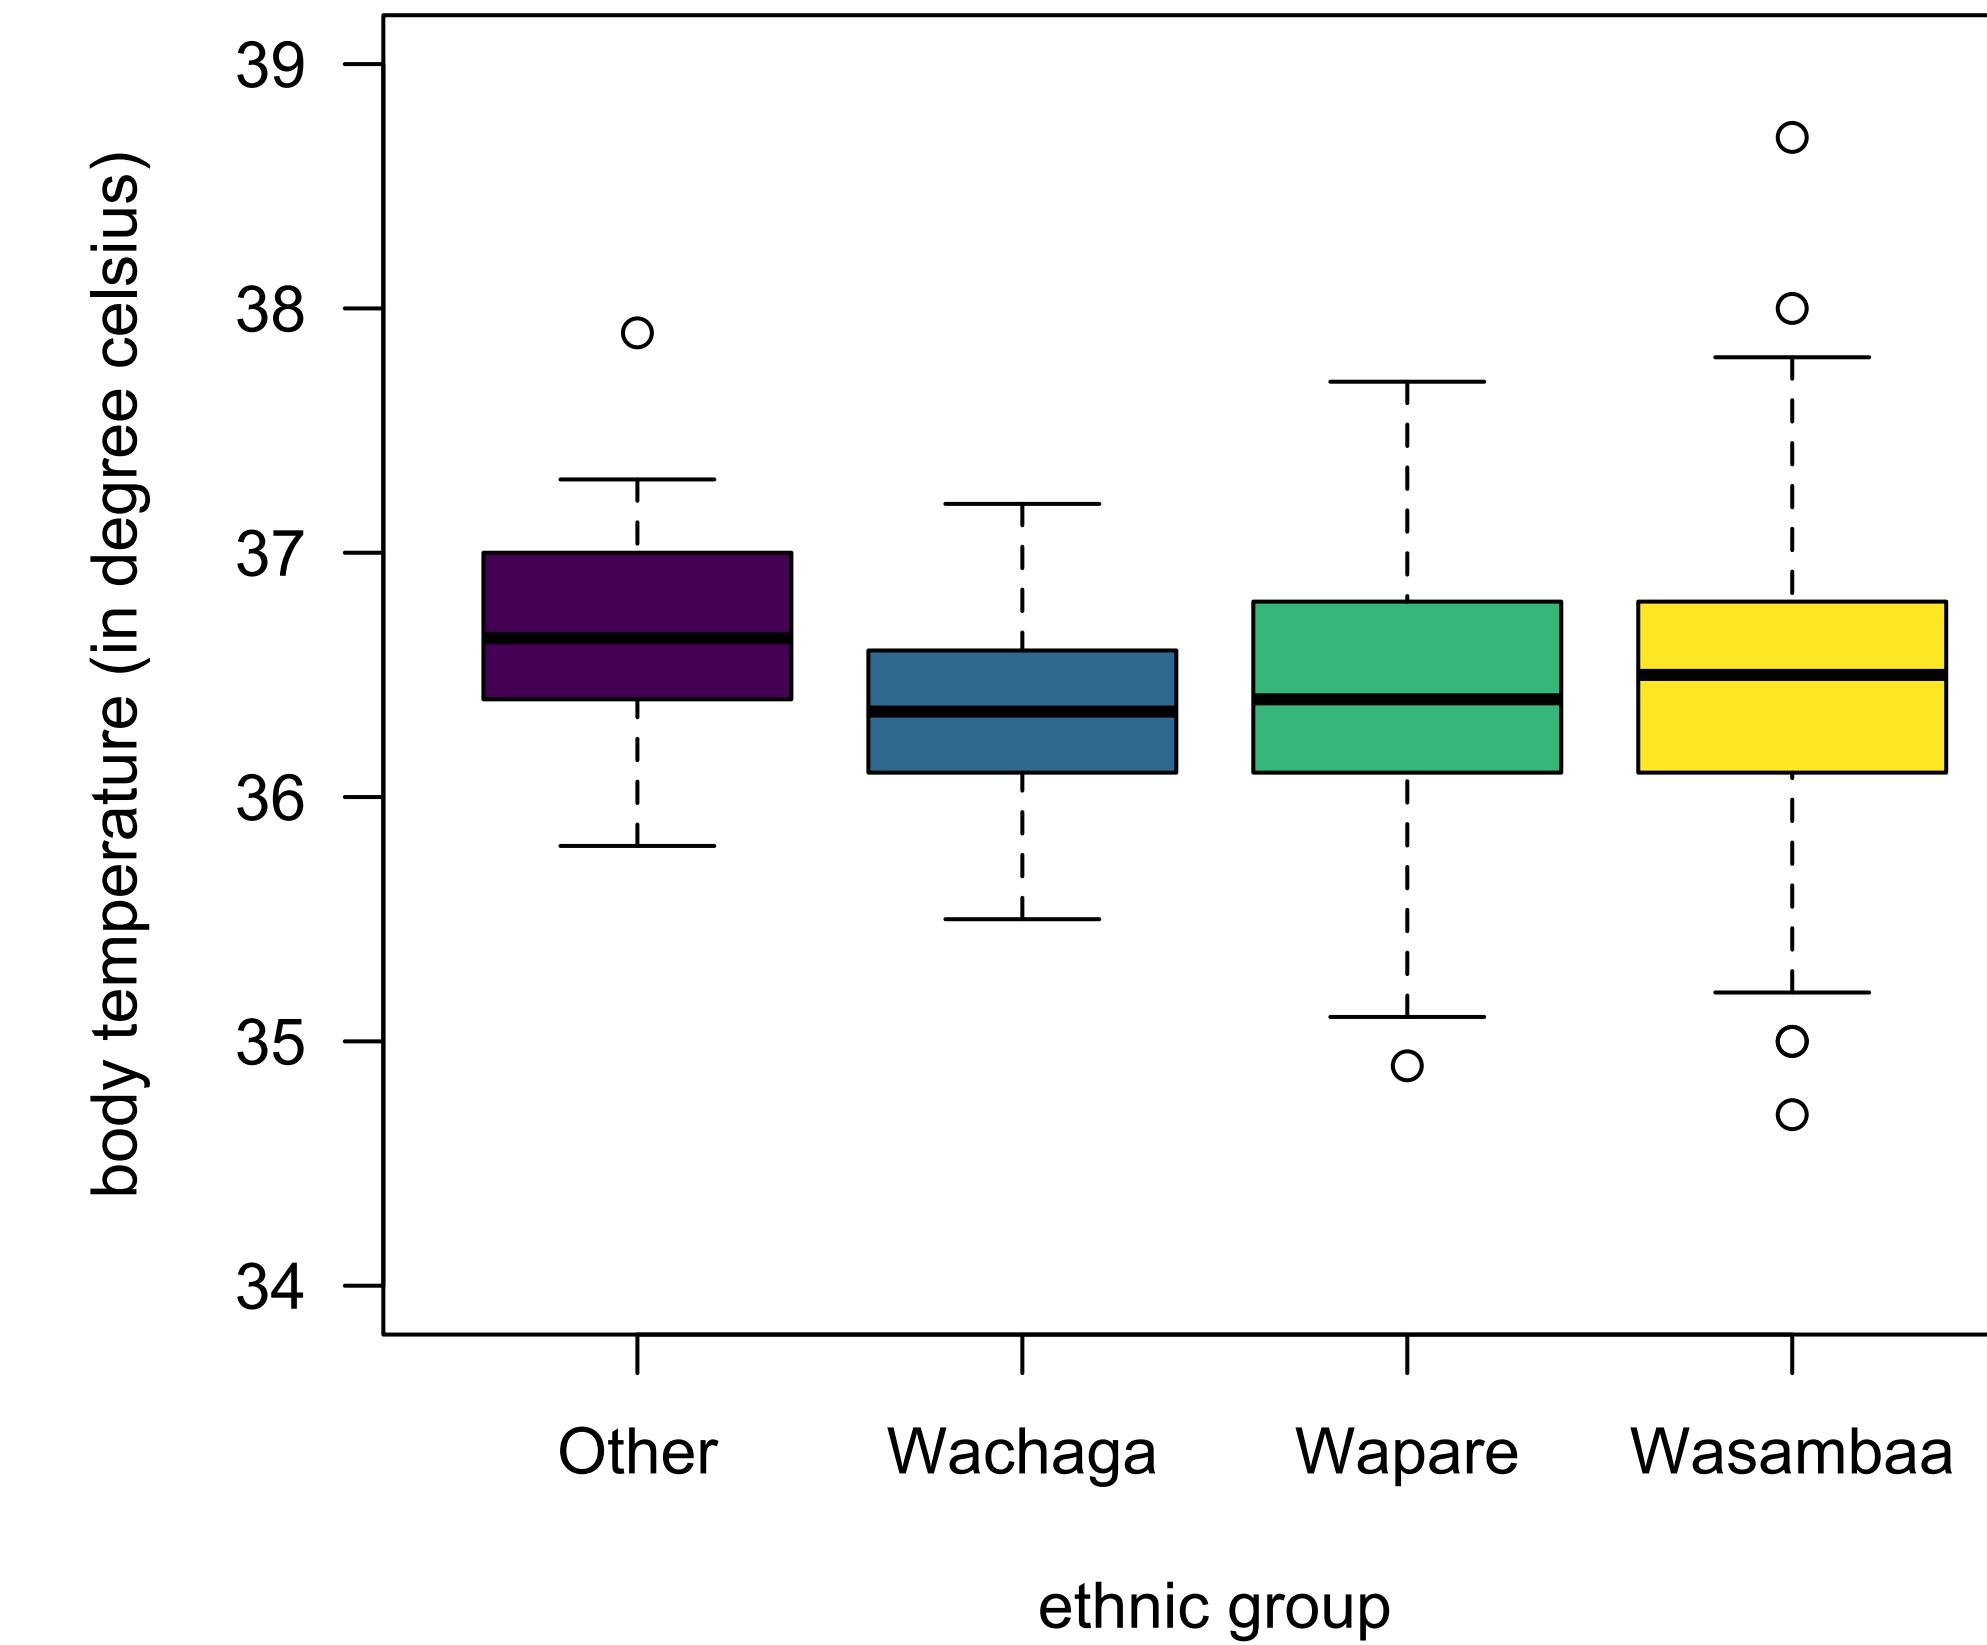

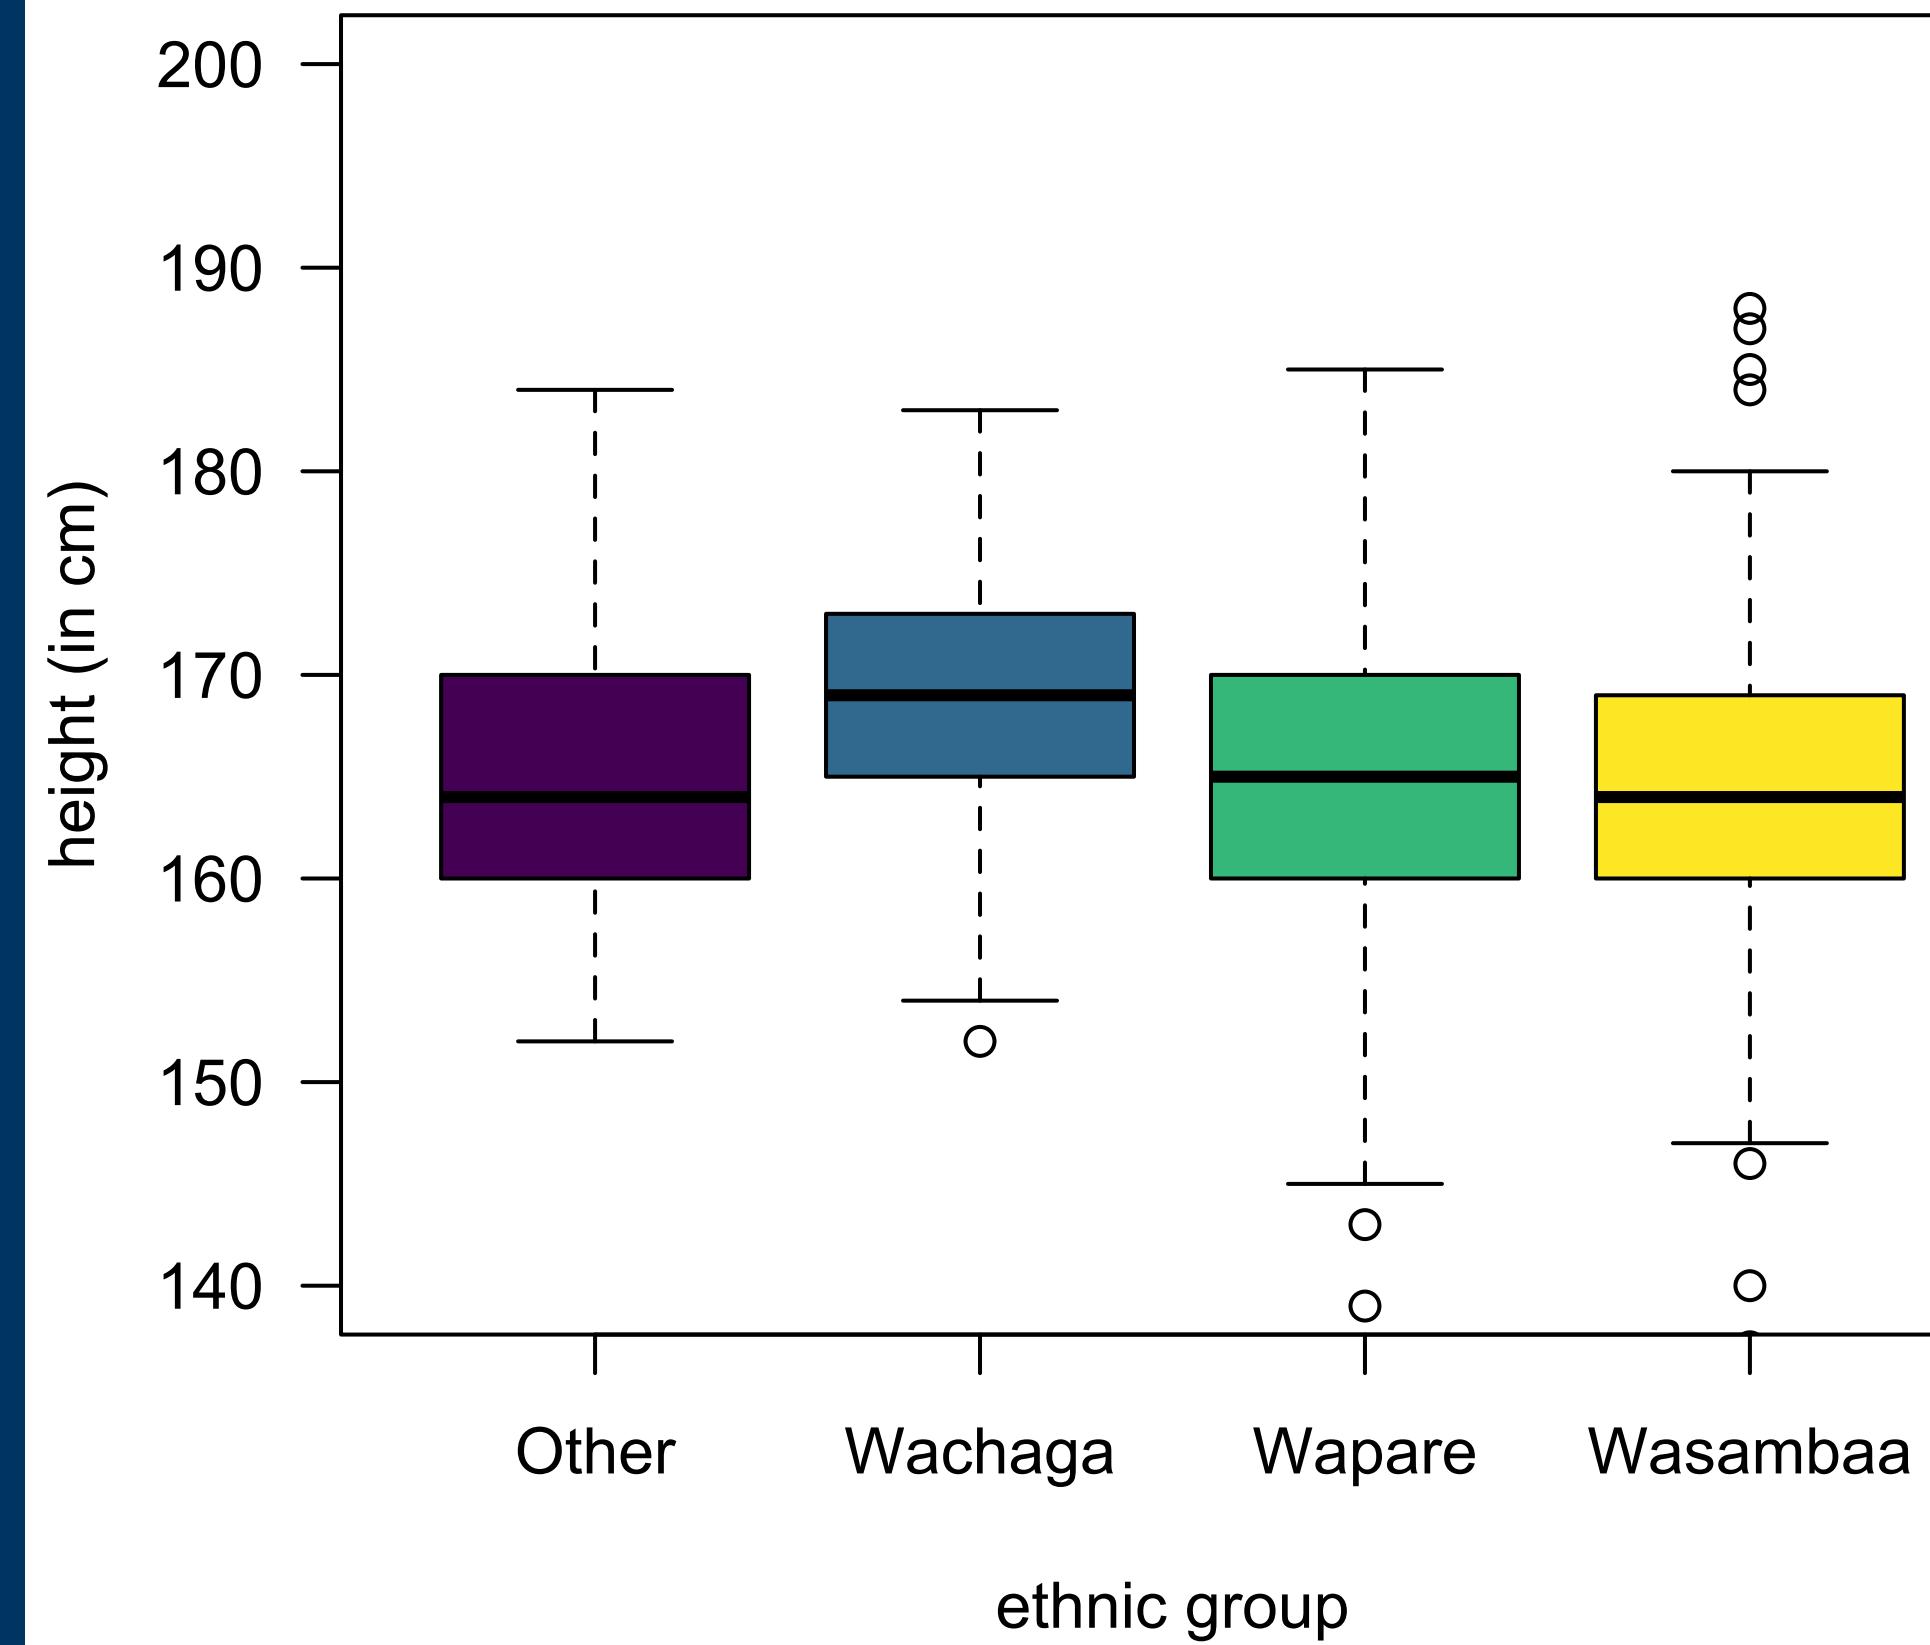

If a genetic marker and the causative gene are in different chromosomes, there is no association between the genetic marker and the causative gene due to independent segregation of chromosomes.

The genetic marker is not associated with the phenotype.

# A bit about quantitative traits

## Male Adults in Northeast Tanzania

What are the genes controlling the height and body temperature of these individuals?

## Fisher's infinitesimal (or polygenic) model

A quantitative trait is affected by a large number of alleles located at different genes.  
The effect of these alleles is additive on the quantitative.

$$Y_i = \alpha_0 + \sum_{j=1}^{\infty} \alpha_j X_{ij} \rightsquigarrow ?$$

where

$X_{ij}$  is the number of alleles in genotype at gene  $j$  in individual  $i$

$\alpha_0$  is the overall average of environmental factors and alleles located at other genes

$\alpha_j$  is the phenotype effect of adding an allele to the genotype at gene  $j$
